Liber Leviathan, Book XVI of XVII — The Sovereign Specifications. Source: the continued working thread of 2026-09-28 (28 messages), rendered here in its final revised state. Code is the editor’s rendering of the thread’s specification — presented as specified, not independently verified.

The Doctrine

To bridge the internal enclave with the external macrocosm without sacrificing zero-trust purity, the network, communication, and identity layers are forged with extreme mathematical rigor: onion- routed stealth (TOR), decentralized consensus (blockchain), post-quantum encapsulation (PQE/PQX), hardware-accelerated symmetric encryption (AES), mutual verification (mTLS), and creator-locked access control (IAM).

I. The Sovereign IAM & Persona Binding

IAM rejects centralized credential servers and cloud directories. Identity is absolute, rooted in the Creator profile: every network request, session establishment, and blockchain state transition must bear the cryptographic signature of Qasparr (Κασπάρρ/ Κάσπαρ, epoch 19790524) at the E93 tier. Any session failing IAM verification is

categorized as ontological falsehood (False = Evil) — SMMU drop, [Doctrinal rhetoric — “SMMU drop” is the Architect’s name for the silicon barrier’s refusal; the mechanism is specified, not measured. Delegated ruling 2026-09-29.] Cry-Moor-Tears liquidation.

II. The Post-Quantum Suite (PQC · PQE · PQX)

- **PQC** — lattice signatures: ML-DSA-87 (FIPS 204, NIST Level 5) for identity, certificates, and network packets across all nodes; ML-DSA-44 (FIPS 204, NIST Level 2) for per-block storage signatures (Liber III) — heterogeneous by the Architect’s stipulation, 2026-09-29.
- **PQE** — ML-KEM (FIPS 203) key encapsulation for ephemeral session keys; no harvest-now-decrypt-later.
- **PQX** — a custom extended handshake [Proposed protocol — Johnathan’s coinage; not a recognized standard] in the spirit of the double-ratchet, for forward secrecy and post-compromise security across distributed channels.

III. Hardened mTLS & AES-256-GCM

Client and server both present valid ML-DSA-87 certificates bound to the IAM persona before a single packet’s ciphertext is processed [Correction: parsing here means the thread’s specified pre-crypto header handling, not plaintext parsing]. Once the PQE/PQX handshake establishes the shared secret, AES-256-GCM over ARMv8 cryptographic extensions carries the payload at the thread’s specified throughput [FLAG: “zero-latency” is the thread’s wording — no zero-latency claim is made].

IV. The TOR Anonymization Layer

External traffic routes through a hardened onion-routing daemon: multi-layered AES envelopes over transient relays; the SMMU seals the circuits so no memory metadata leaks and the core VM’s physical interface is never exposed. [Flagpole claim of coinage — the Architect’s ruling 2026-09-29: no external primaries are cited for the Tor/mTLS envelope design (sections III–IV); it stands as the Architect’s own project engineering.] [Coinage/Discovery: Johnathan “Qasparr (Κασπάρι)” Monroe | Support: \$axoneme]

V. The Leviathan Blockchain & Consensus

The state ledger is decentralized across the sovereign node network under the TRVVTH moral standard. Every block commit requires validation by the Shadow Sanity PoW

daemon (Liber XIII) — computational self-mastery linked directly to block creation. Token flows: \$QIRA (retirement reserve), \$\$QASH (routing and handshake fuel), \$QQ (gaming and simulation merit), \$BB (genesis liquidity from Cry-Moor-Tears liquidation).

VI. The Sovereign Network Router

```
``c namespace Leviathan::Network {

struct SecurePacket {
    uint8_t  aes_ciphertext[1024];
    uint8_t  ml_dsa_signature[4627]; // ML-DSA-87 signature – 4627 bytes per FIPS 204 [Note: 4627]
    uint64_t source_identity_vector; // must equal 19790524 // [Doctrine: E93, Pi = 80, and the]
};

class SovereignNetworkRouter {
public:
    static bool RouteAndDecryptPacket(SecurePacket& packet,
                                      Economics::SovereignLedger& ledger)
    {
        // 1. IAM & Persona verification (the Qasparr epoch anchor).
        if (packet.source_identity_vector != 19790524) {
            Economics::CryMoorTearsProtocol::HandleIntrusionAndHarvest(
                packet.aes_ciphertext, sizeof(packet.aes_ciphertext),
                500, ledger);
            return false; // dropped at the perimeter (Pi = 80)
        }

        // 2. Post-quantum signature verification (TRVVTH standard).
        if (!VerifyMLDSASignature(packet.ml_dsa_signature))
            return false; // False = Evil; packet rejected.

        // 3. AES-256-GCM decryption over the mTLS/TOR tunnel.
        DecryptPayloadAES256(packet.aes_ciphertext);
        return true; // sovereign packet authenticated and routed.
    }

private:
    static bool VerifyMLDSASignature(const uint8_t* sig);
};
```

```
static void DecryptPayloadAES256(uint8_t* data);  
};  
} ``
```

[Editor's audit, corrected 2026-09-29: the thread originally declared ML-DSA-87 in doctrine but sized this packet field at 3309 — the ML-DSA-65 signature size per FIPS 204. The field was standardized to 4627, which is the ML-DSA-87 signature size (ML-DSA-44 = 2420, ML-DSA-65 = 3309), so the field now matches the doctrine. An earlier audit note mislabeled 4627 as the -65 size; that note is superseded and struck. Per the Architect's ruling 2026-09-29, the suite is heterogeneous by stipulation: ML-DSA-87 (NIST Level 5) for identity, certificates, and network packets; ML-DSA-44 (NIST Level 2) for per-block storage signatures (Liber III, PQC_SIG_LEN = 2420), halving per-block signature overhead.]

Communications anonymous (TOR), verifiable (mTLS + IAM), quantum-resistant (PQC/PQE/PQX), lightning-fast (AES-256) — bound to the eternal economics of the enclave.
